## SUMMARY

A detailed investigation of the flight buffeting response of the F-111A was performed in two phases. In Phase I stochastic analysis techniques were applied to wing and fuselage responses for maneuvers flown at subsonic speeds and wing leading-edge sweep of 26 degrees. Power spectra and r values of response were obtained for:

- (1) vertical accelerations at the wing tips, the center of gravity and the pilot's seat,
- (2) lateral accelerations at the center of gravity and the pilot's seat,
- (3) vertical shear, bending moment and torsional moment at 4 spanwise locations on the right variable sweep wing panel.

In Phase II the analyses were extended to include maneuvers flown at wing leading-edge sweep values of 50 and 72.5 degrees at subsonic and supersonic speeds and the responses examined were expanded to include vertical shear, bending moment, and hingeline torque of the left and right horizontal tails.

This volume presents tabulations of Power Spectral Density (PSD) data for all of the flight points examined during the Phase II flight data analysis. Detailed descriptions of the aircraft, the flight instrumentation and the analysis techniques

are given. Measured and calculated vibration mode frequencies are also presented to assist in further interpretation of the PSD data.

The major conclusions of the investigation are:

- (1) The structural response to buffet during moderate to high-g maneuvers is very complex. Many natural symmetric and antisymmetric natural vibration modes (and perhaps asymmetric modes) can be excited to significant levels of response.
- (2) An array of different types of sensors and locations of the sensors is needed to adequately describe the structural response during buffet investigations.
- (3) The modal content of the response varies with sensor type and location and also can vary with angle of attack, wing sweep and Mach number. The variations in modal content are attributed to the variations in the spatial extent and phase relationships of the separated flows
- (4) At low wing sweep there are significant differences in the variations of rms response with angle of attack for different Mach numbers. The largest magnitudes of response were measured during flight

conditions where shock induced flow separations were present

- (5) In general, the rise in rms response with angle of attack becomes smaller as wing leading edge sweep is increased
- (6) The buffeting loads on the wing are small relative to the maneuver loads at the most inboard measuring station but become larger near the wing tip. The larger relative rms values of response near the tip are attributed to higher frequency modes and thus should be considered important from a fatigue standpoint with respect to secondary structure.

The data obtained in this investigation were used to help formulate and evaluate a method of predicting buffeting response which uses wind tunnel measurements of the fluctuating pressures on a "rigid" wing as the input forcing function.

The entire investigation is documented in eight reports which are listed below

## SECTION 1

### INTRODUCTION

A detailed investigation of the structural response of an F-111A aircraft to buffet during moderate to high-g maneuvers was accomplished in two phases. In Phase I (References 1, 2, 3) the response characteristics with the variable sweep wings set at a nominal leading-edge sweep of 26 degrees were examined for the seven maneuvers described in Table 1.

Power spectra and rms values of response were determined for 19 different measurement items consisting of vertical accelerations at the wing tips, the center of gravity and the pilot's seat, lateral accelerations at the center of gravity and the pilot's seat and vertical shear, spanwise bending moment, and torsional moment at 4 different spanwise stations on the right wing.

The conclusions reached from the Phase I Study were:

- (1) The structural response during buffet is very complex. Many natural vibration modes both symmetric and antisymmetric can be excited during a maneuver in which flow separation occurs on the wings.
- (2) The spectral content of the response varies with the type of sensor, the location of the sensor and in some cases with angle of attack.

- (3) The variations of rms values of response with angle of attack can be quite different for different values of Mach number. The largest measured responses occurred under conditions where shock-induced flow separations occurred on the wing. In particular the torsional response was significantly higher than anticipated on the basis of previous buffet studies.
- (4) The magnitudes of the wing bending and wing shear responses at the most inboard measurement station are small relative to the maneuver loads. Near the wing tip the buffet loads are a much larger percentage of the maneuver loads.
- (5) Horizontal tail vibration modes appear to make significant contributions to the fuselage responses.

In Phase II the structural responses at nominal wing leading-edge sweeps of 50 and 72.5 degrees were analyzed. Vertical shear, bending moment and hingeline torque at the root of the left and right horizontal tails were analyzed in addition to the 19 measurement items examined in Phase I. All 25 items were studied for six maneuvers listed in Table 2. In addition the horizontal tail responses were analyzed for two wind up turn maneuvers from the Phase I Study as listed in Table 2.

Volume I (NASA CR-152112) summarizes the Phase II investigation in detail. Volume II (NASA-CR-152113) presented Power Spectral data in plotted forms. This Volume (NASA CR-152114) presents tabulations of power spectral density (PSD) data for all of the flight points and instrumentation items analyzed in the Phase study. Sufficient information about the aircraft, the flight instrumentation and the analysis techniques is presented to allow the reader to perform additional analyses if desired.

## SECTION 2

### AIRCRAFT DESCRIPTION

The test aircraft was F-111A Number 13. A drawing showing the general features of the aircraft is presented in Figure 1. Detailed geometry associated with the aircraft and its components appears in Table 3. The aircraft has a variable sweep wing and a convention was adopted early in the development program that all aerodynamic coefficients would be referenced to geometric characteristics at a specific wing sweep, namely,  $\Lambda_{LE} = 16$  degrees. The variations of some key geometric characteristics of the wing with wing leading-edge sweep angle are presented in Figure 2.

Although the aircraft is fitted with a high-lift system consisting of multisegment leading-edge slats and multisegment double-slotted trailing-edge flaps, these devices were in their retracted positions for all maneuvers analyzed in this study.

Two-segment upper surface spoilers on each wing are used at low wing sweeps in addition to differentially controlled all-movable horizontal tails to achieve roll control.

The aircraft has a three-axis stability augmentation system which was operational on all maneuvers analyzed in this investigation.

SECTION 3  
AIRCRAFT INSTRUMENTATION

The instrumentation system installed in the aircraft consisted of two 30 track and one 14 track FM analog magnetic tape recorders and various transducers throughout the airplane. IRIG B time reference signals were recorded on each tape recorder to provide time correlation. The general locations of the accelerometers pertinent to the buffet study are shown in Figure 3. The actual locations in terms of aircraft geometry references are listed in Table 4.

The characteristics of the accelerometers most of which were commercially available units are indicated in Table 5. The accuracies quoted refer to the nominal flat frequency response up to the limit frequency quoted. No calibration data exist above the quoted limit of flat frequency response, however, the natural resonant frequencies are well beyond 100 herz for all of the accelerometers.

The locations of the wing strain gage sensors pertinent to the buffet study are shown in Figure 4. Shear, bending moment and torque were measured at each of the four indicated wing stations on the right wing.

The locations of the strain gage sensors for the horizontal tail loads measurements are shown in Figure 5. Vertical shear bending moment and hingeline torque were measured at the

root of both the left and right horizontal tails. The sensitivities of the wing and tail loads measurements were governed by the fact that the loads were to be measured during maneuvers at load factors up to the maximum capability of the aircraft. As a consequence the signal-to-noise ratios for the present buffet studies were lower than is desirable. The calibration slopes for each channel of information are shown in Table 6.

In several cases the frequency response upper limit for the measurements was set by the subchannel characteristics of the flight recording system. Table 7 lists the appropriate nominal limit frequency of subchannel arrangements for each flight selected for detailed analysis

Other pertinent measurements such as angle of attack, Mach number, altitude, fuel remaining, horizontal tail position and spoiler position were also recorded on the FM tapes

## SECTION 4

### BASIC DATA PROCESSING METHODS

During the Loads Demonstration Flight Program, the FM analog magnetic tapes containing raw flight test data were processed by automated processing techniques. The data were first played out on strip chart recorders for instrumentation verification. Next, the data were digitized at sample rates of up to 20 samples per second under computer control. Either 10 or 20 samples per second were used for the data pertinent to this study. The digitized data were then scaled, calibrated and output in computer listings and computer tapes for additional processing on an IBM System/360. Second generation computer runs were made to obtain corrected flight condition data such as gross weight, Mach number, altitude, dynamic pressure and fuel distribution at 1-second intervals.

Microfilm records of the computer listings from the original flight program data reduction were used in the present program to make plots of angle of attack, normal load factor, Mach number and dynamic pressure as functions of flight time and to identify the gross weights and altitudes for the selected flight maneuvers. The Mach number, altitude and dynamic pressure data include corrections for position error. The angles of attack from the basic reduction are indicated angles and do not include the effect of

upwash at the nose boom. A correction formula to account for the upwash is

$$\alpha_T = 0.318 + 0.931 \alpha \text{ (degrees)}.$$

It was not considered fruitful to apply this correction in the various plots presented in this report because corrections to the wing angle of attack due to structural flexibility are much larger in magnitude and can only be approximated. Both corrections were considered in selecting the time intervals for the stochastic analysis in Phase II in order to obtain agreement with existing wind tunnel model data insofar as possible.

Time histories were made of about 30 items of instrumentation measurements which were considered pertinent to the buffet study. Examples of each of the strip chart records have been previously presented in the Phase I report (Reference 1). These records were used to aid in the process of selecting the maneuvers for the Phase II Study. The records for the Phase II Study maneuvers were in general too large to be legibly reproduced on an unfolded page.

## SECTION 5

### FLIGHT CONDITIONS FOR DETAILED ANALYSIS

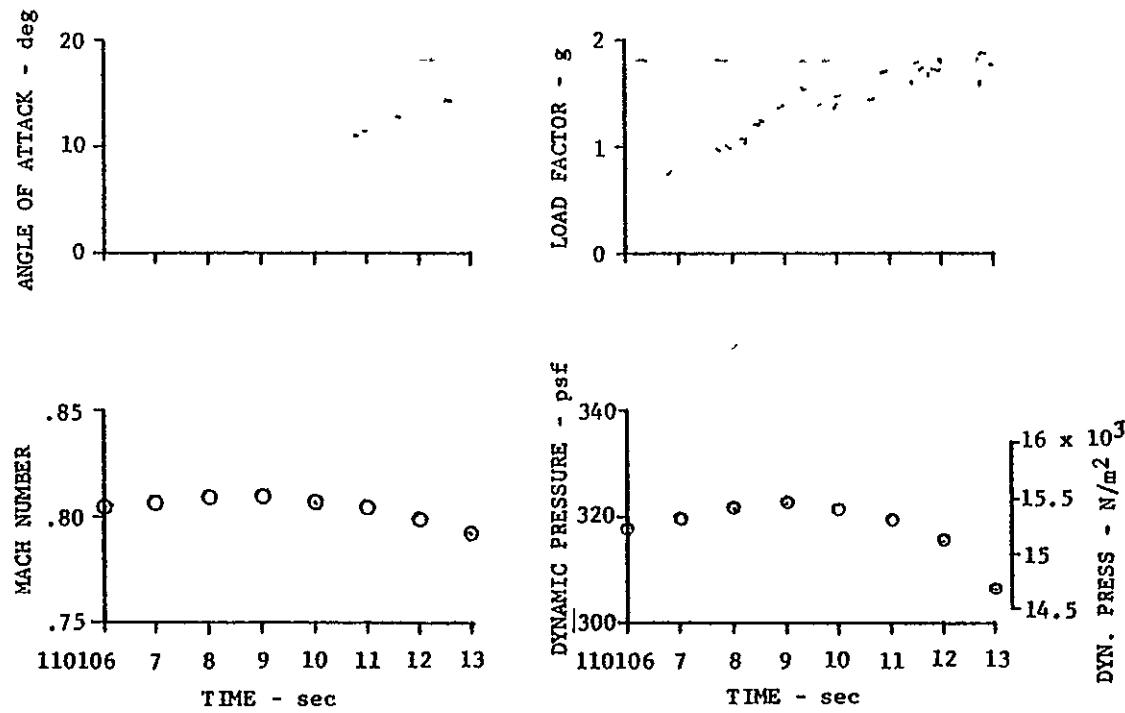

In the Phase II Study the major criterion for selecting the particular flight maneuvers was matching insofar as possible conditions of wing sweep, Mach number and angle of attack for which wind tunnel data already existed. It was considered important to use maneuvers for at least two additional wing sweeps and at both subsonic and supersonic speeds. The four wind up turn maneuvers listed in Table 2 were selected on that basis.

A question had arisen in the Phase I Study with respect to the character of the structural responses as deduced from relatively short time samples. The two slowdown turn maneuvers listed in Table 2 were chosen to examine whether or not short time samples and longer time samples gave consistent results.

Variations of angle of attack, load factor Mach number and dynamic pressure with flight time are presented in Figure for each of the selected maneuvers.

Table 8 lists the segments of each maneuver selected for detailed analysis. In most cases the time duration of the records ( $\Delta T$ ) is one second, but some longer records were used. The table also lists the indicated angle of attack at the start

of each record ( $\alpha_1$ ), at the end of each record ( $\alpha_2$ ) and in a few cases the maximum angle of attack occurring during the record ( $\alpha_{\max}$ ). A nominal angle of attack ( $\alpha_{\text{nom}}$ ) has been assigned to each data segment which is used later to plot trends in the variations of instrument responses with angle of attack.

## SECTION 6

### STOCHASTIC ANALYSIS TECHNIQUES

The analysis techniques used in this study are compatible with American National Standard (ANS S2.10-1971) recommended methods for analysis and presentation of shock and vibration data. A quick-look examination was performed on each time-history measurement to determine the data classification, degree of stationarity, record length and recoverability.

#### Measurements

Data reduction was performed on the following data:

1. Shear, bending moment and torsion at four wing stations, (12 measurements).
2. Shear, bending moment and hingeline torque at the root of both left and right horizontal tails (6 measurements)
3. Two wing tip accelerometers (verticals)
4. Two c.g. vertical and one c.g. lateral accelerometers.
5. Pilot's seat vertical and lateral accelerometer.

The stochastic analysis performed on these items was limited to power spectral densities (PSD) and average rms values for each data sample. A total of 660 PSD's were processed in Phase II.

In addition a few narrow band time histories were made for selected wing instrumentation items.

## Special-Purpose Processing

A block diagram of the special-purpose stochastic equipment is shown in Figure 7. The FM signal is discriminated to recover the analog signal. Band-pass filters at 3 Hz and 100 Hz (48 dB per octave) were used to reject unwanted frequencies and to minimize aliasing effects on the sampled data. The data is calibrated at this point. The T/D 100 analyzer was used to compute the PSD's. The stochastic algorithm utilized by the T/D 100 to perform this function is discussed below.

Prior to the Phase II Study the equipment was modified to achieve a direct interface with an SEL-810A mini-computer which then permitted direct recording of the output of the T/D-100 on magnetic tape. The tapes were then used as input to a plotting routine.

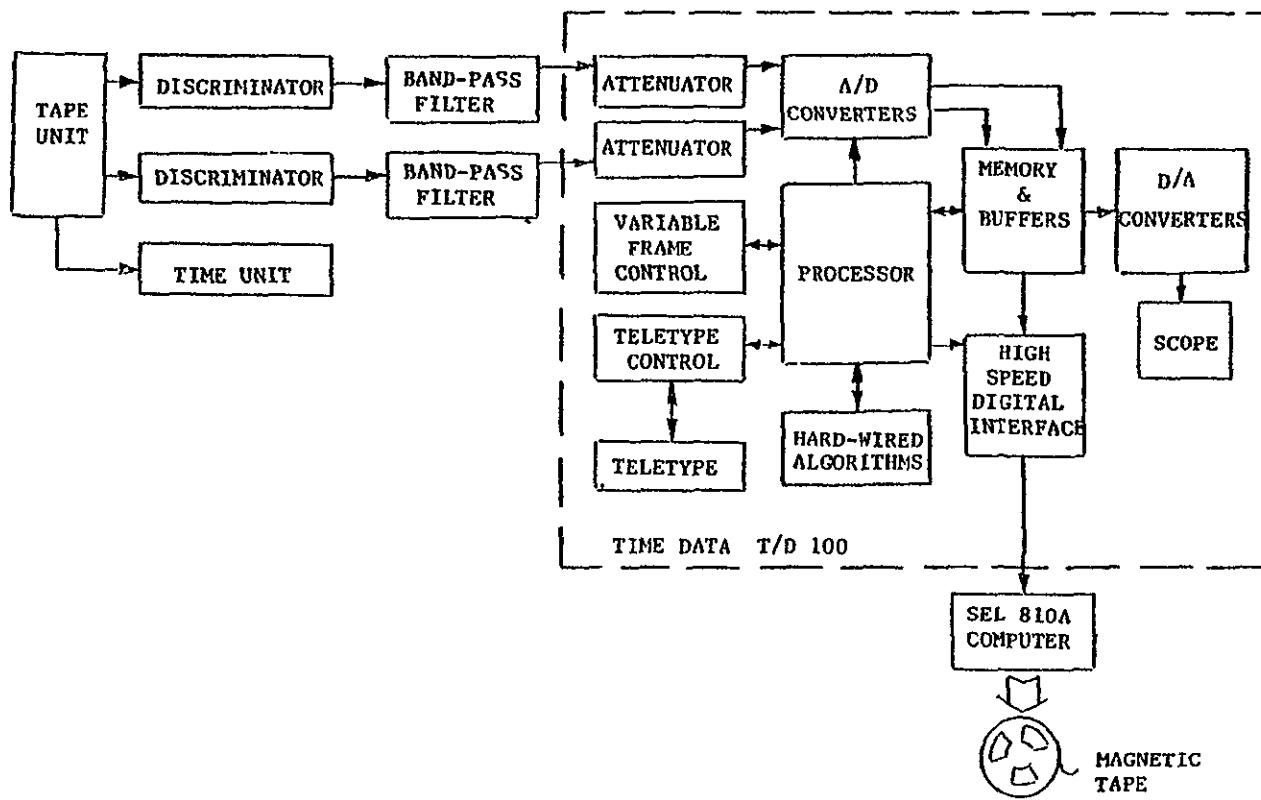

Figure 7. STOCHASTIC SPECIAL-PURPOSE EQUIPMENT

ORIGINAL PAGE IS  
DE POOR QUALITY

### Auto-Spectral Density (PSD)

The T/D.100 computes the PSD coefficients by first approximating the complex Fourier transform of the input signal. The Fourier transform of the time-domain input function  $x(t)$  is given by:

$$G(jf) = \int_{-\infty}^{+\infty} x(t)(\cos 2\pi ft - j \sin 2\pi ft) dt \quad (1)$$

where  $j = \sqrt{-1}$ . Since the time-domain input is sampled and quantized in the analyzer, and only a finite number of samples are available, the finite transform is used, and separated into its real  $P(f)$  and imaginary  $Q(f)$  components can be written as follows:

$$P_T(f) = \int_{-T/2}^{T/2} x(t) \cos 2\pi ft dt \quad (2)$$

$$Q_T(f) = \int_{-T/2}^{T/2} x(t) \sin 2\pi ft dt \quad (3)$$

where  $T$  is the length of the input frame, which is assumed to be centered about time  $t=0$ .

Replacing the continuous input,  $x(t)$ , with a set of  $2N+1$  discrete samples at intervals of  $t_0 = \frac{1}{2N}$ , and replacing the sinusoidal functions by corresponding values, the continuous integrals may be expressed as the sum of products:

$$P(kf_o) = \sum_{n=-N}^{+N} x(nt_o) \cos [2 \pi kf_o(nt_o)] \quad (4)$$

$$Q(kf_o) = - \sum_{n=-N}^{+N} x(nt_o) \sin [2 \pi kf_o(nt_o)] \quad (5)$$

where  $k$  is a series of  $2N$  integers and  $f_o$  is the base frequency which is equal to  $\frac{1}{2T}$ .

The PSD coefficients  $[S(kf_o)]$  are then computed from (4) and (5) by the equation:

$$S(kf_o) = |P(kf_o)|^2 + |Q(kf_o)|^2 \quad (6)$$

Average rms ( $\Psi_T$ )

The average rms of the input signal is calculated from the PSD coefficients  $[S(kf_o)]$  by the following equation:

$$\Psi_T = \sqrt{f_o \sum_{k=0}^{2N} S(kf_o)}$$

where  $f_o = \frac{1}{2NT}$  is the base frequency or analysis bandwidth.

## SECTION 7

### PRESENTATION OF TABULATED DATA

During the course of the Phase II study, approximately 660 power spectra were obtained. These data have two primary uses. First, they permit identification of the significant modal contributions through comparison with ground vibration test data obtained in the F-111 development program. Second, they provide the data base for assessment of prediction methods.

The spectral content of the structural responses is related to the natural vibration modes. Summaries are presented of the natural vibration mode frequencies as determined from ground vibration tests and also as calculated using a finite element representation of the aircraft structure for each wing sweep. These data are useful for interpreting the power spectra.

#### Natural Vibration Modes

The measured natural vibration modes and their associated frequencies are presented in Tables 9 through 11 for wing sweeps of 26, 50, and 72.5 degrees. These data were obtained during extensive ground vibration tests conducted on aircraft in the F-111 development program and are taken from References 4 and 5. In addition, calculated modes were determined for specific flight conditions for use in the prediction method development and evaluation portions of the contracted investigation. The calculated

modes are presented in Tables 12 through 19. Further discussion of the analytical effort appears in References 6, 7, and 8.

#### Power Spectral Density Tabulated Data

In this Section all power spectral density data obtained during the Phase II investigation are presented in tabulated form for the convenience of those who might wish to perform analyses and/or comparisons other than those presented in NASA CR-152112 and NASA CR-152113.

The arrangement of the tabulated data is as follows.

Each set of PSD's correspond to a particular instrumentation item at a particular flight point identified in Table 8. The progression in the record number is continuous within a given maneuver. For example, if there are 5 points listed in Table 8 for a given maneuver then records 1-5 are for points 1-5 for the first instrumentation item, records 6-10 are for points 1-5 for the second instrumentation item, etc. The last record number listed for a particular maneuver gives the total number of PSD sets obtained for that maneuver.

The item code corresponds to the instrumentation code listed in Table 6. The second line of each data set identifies the particular point within the maneuvers listed in Table 8. The flight number identification is obvious. The frame number and record length correspond to the start time,  $T_1$ , and time interval,  $\Delta_T$ , listed in Table 8.

Although data are presented for frequencies from 1 to 100 Hz in each record, the frequency limits for the particular items of instrumentation and flights listed in Table 7 should be observed when working with the tabulated or plotted data.
